

Abstract:

The invention relates to a method for performing link adaptation in a communication system, in which two communication devices are arranged to communicate with each other in order to transmit information at least partly in a wireless manner. Packets are formed of the information to be transferred, and the packet error rate is defined. In the communication system, at least two different modulation modes can be selected for the connection. The method utilizes fuzzy control in the selection of the modulation mode, wherein at least one of the used variable is said defined packet error rate.
